

Mail

Install Exim

```
# yum install -y exim
```

To assist in testing the mail configuration

```
# yum install -y mailx
```

Configure Exim

So far it looks like the default config works. And exim comes with no command line utility for configuration like `dpkg-reconfigure exim4-config` like debian, so if we have to modify settings, it'll get messy

Test Exim

Use a real email address below so you can see if you get the email

```
# Mail -v someone@gmail.com
```

If you wish, you may uninstall the command line mail utility after this test.

```
yum remove mailx
```
