

Installation

Target Audience

This document and the installation and maintenance of a HUBzero system has a target audience of **experienced** Linux administrators (preferably experienced with RedHat or CentOS distributions).

Minimum System Requirements

HUBzero (RedHat) installations require one or more dedicated hosts running RedHat or CentOS version 6.

A typical starter HUBzero installation might consist of a single physical server with dual 64-bit quad-core CPUs, 24 Gigabytes of RAM and a terabyte of disk.

Production systems should try to not limit hardware resources, HUBzero is designed to run on systems with many CPU cores and lots of RAM. If you are looking for a system to run a small site with limited physical or virtual resources this is probably not the system for you. However, for demonstration or development purposes we often create VM images with less than a gigabyte of RAM and 5 gigabytes of disk. While fully functional, these virtual machines would only be suitable for a single user doing development or testing.

System Architecture

All hardware, filesystem partitions, RAID configurations, backup models, security models, etc. and base configurations of the hosts email server, SSH server, network, etc. are the responsibility of the system administrator managing the host.

The Hubzero software expects to be installed on a headless server from a minimal ISO with only one network interface (required by OpenVZ) with an MTU no less than '1500'. System accounts must not be created with an id of 1000 or greater - more about that in a forthcoming section.

Linux

Install Basic Operating System

Advanced Linux system administrator skills are required, please read carefully. Selecting all the default configurations during the operating system installation may not be correct.

The latest version of RedHat Enterprise Linux 6 or CentOS 6 64-bit should be downloaded and installed. Do not install a default LAMP environment or other server packages, those will be taken care of in later steps of the HUBzero install.

Hubzero packaging support is for the amd64 (64 bit) Intel architecture only.

System reboots are required to complete the installation. Be sure to remove the install disk or reset your server's boot media before rebooting.

The precise server configuration (such as disk partitioning, networking, etc) is dependent on how the hub is to be used and what hardware is being used, all the possible configuration options are not specifically outlined here. This installation guide outlines a very basic configuration but may not be suitable for larger sites. For larger sites, it is generally expected that the hub will be managed by an experienced Linux administrator who can help setup your site to meet your specific requirements.

All hardware, filesystem partitions, RAID configurations, backup models, security models, etc. and base configurations of the hosts email server, SSH server, network, etc. are the responsibility of the system administrator managing the host.

The following instructions only instruct how to install Hubzero software. At a minimum a "Basic Server" host, ideally from a minimal ISO, is required with network access.

The Hubzero software expects to be installed on a headless server without a Graphical User Interface.

Configure Networking and DNS

Configure you host's network as desired. A **FQDN and an SSL certificate for the domain is required**. A static IP is highly recommended (a common basic configuration for a web server) as well.

The Hubzero middleware uses an IP addresses in the 192.168.0.0/16 subnet, do not use a conflicting host IP during network configuration.

Set hostname

INSTALLATION

Throughout this documentation you will see specific instructions for running commands, with part of the text highlighted. The highlighted text should be modified to your local configuration choices. (e.g. replace "example.com" with the fully qualified hostname of your machine).

HUBzero expects the `hostname` command to return the fully qualified hostname for the system. This step may be skipped if previously configured.

```
sudo hostname hubdomain.org
```

Make the change permanent (or manually edit `/etc/sysconfig/network`):

```
sudo sed -i "s/HOSTNAME=.* /HOSTNAME=hubdomain.org/g" /etc/sysconfig/network
```

Delete local Users

HUBzero reserves all user ids from 1000 up for hub accounts. As part of the app middleware every account must map to a corresponding system account. Therefore when starting up a hub it is required to remove all accounts that have user ids 1000 or greater. New RedHat/CentOS installations typically do not setup a non root account during setup, but if you have any accounts added to the system, those accounts can be removed as follows:

```
sudo userdel username  
sudo rm -fr /home/username
```

If you require additional system accounts, they should use user and group ids in the range of 500-999 (these will not interfere with hub operations).

Update the initial OS install

```
sudo yum update -y
```

Disable SELinux

Hubzero does not currently support SELinux. Since the default install of RHEL turns it on, we have to turn it off.

```
sudo sed -i 's/^SELINUX=.* /SELINUX=disabled/g' /etc/selinux/config
```

Reboot the system for this change to take effect

```
sudo reboot
```

Yum repository setup

Configure the hubzero repository configuration package

For RedHat Enterprise Linux 6

```
sudo rpm -Uvh http://packages.hubzero.org/rpm/julian-el6/hubzero-julian-repo-2.2.5-1.el6.noarch.rpm
```

```
sudo rpm -Uvh http://download.fedoraproject.org/pub/epel/6/x86_64/epel-release-6-8.noarch.rpm
```

```
sudo subscription-manager repos --enable rhel-server-rhsc1-6-rpms
```

```
sudo subscription-manager repos --enable rhel-6-server-optional-rpms
```

For CentOS 6

```
sudo rpm -Uvh http://packages.hubzero.org/rpm/julian-el6/hubzero-julian-repo-2.2.5-1.el6.noarch.rpm
```

```
sudo sh -c "cat > /etc/yum.repos.d/rh-php56.repo << 'EOT'
[hubzero-php56]
name=Hubzero PHP56
baseurl=http://packages.hubzero.org/rpm/rh-php56/6Server
enabled=1"
```

INSTALLATION

```
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-SIG-SCLo
EOT"
```

```
sudo yum install -y epel-release centos-release-scl-rh
```

Install Support Packages

```
sudo yum install -y sudo dirmngr software-properties-common
```

Firewall

Install

```
sudo yum install -y hubzero-iptables-basic
```

```
sudo service hubzero-iptables-basic start  
sudo chkconfig hubzero-iptables-basic on
```

HUBzero requires the use of iptables to route network connections between application sessions and the external network. The scripts controlling this can also be used to manage basic firewall operations for the site. The basic scripts installed here block all access to the host except for those ports required by HUBzero (http,https,http-alt,ldap,ssh.smtp,mysql,submit,etc).

Database

MySQL Database Installation

```
sudo yum install -y hubzero-mysql
```

```
sudo service mysqld start  
sudo chkconfig mysqld on
```

Configure

Default configuration works well for starters. But for optimal performance you will need a database administrator capable of tuning your database to your hardware configuration and site usage.

Mail

Install Postfix

```
sudo yum install -y postfix
```

```
sudo service postfix start  
sudo chkconfig postfix on
```

Test

```
sudo postfix check
```

If the 'postfix check' command returns anything, resolve the reported issues with the Postfix installation before continuing.

Configure Postfix

Configure Postfix as desired. The default installation may only handle mail on the localhost.

Web Server

Install Apache Httpd Web Server

```
sudo yum install -y httpd
```

```
sudo systemctl start httpd
```

```
sudo systemctl enable httpd
```

PHP

Install

We need to install PHP

```
sudo yum install -y hubzero-php
sudo service rh-php56-php-fpm start
sudo chkconfig rh-php56-php-fpm on
```

CMS

Installation

```
sudo yum install -y hubzero-cms-2.2
```

Configuration

```
sudo hzcms install hubname
```

It is necessary to immediately run the updater to apply fixes that have not been incorporated into the initial installation.

```
sudo hzcms update
```

SSL Configuration

The default SSL certificate is meant for evaluation purposes only. For a production Hub, you will need to obtain a certificate from a provider. A certificate may contain two or three pieces: a public certificate, a private key, and sometimes an intermediate certificate.

Once you obtain the certificate, install their respective sub-directories in the **/etc/ssl** directory.

After the certificates are installed, you will need to modify the Apache configuration template located in **/etc/httpd/sites-m4/{hubname}-ssl.m4**.

Replace SSLCERTFILE with the path to your SSL certificate.

```
SSLCertificateFile /etc/ssl/path/to/cert
```

Replace SSLCERTKEYFILE with the path to your SSL key.

```
SSLCertificateKeyFile /etc/ssl/path/to/key
```

If you have an intermediate certificate:

INSTALLATION

remove line 186: `ifdef(`SSLCERTCHAINFILE',`
remove line 188:)dnl`

Replace SSLCERTCHAINFILE with the path to your chain certificate.
`SSLCertificateChainFile /etc/ssl/path/to/cert`

Once the paths have been updated, reconfigure the CMS.

```
sudo hzcms reconfigure hubname
```

```
sudo /etc/init.d/apache2 restart
```

If you are using the HTML5 VNC Proxy Server, [you must update your certificate settings as well.](#)

Test

The default installation of the CMS uses a self signed SSL certificate. Some browsers will not accept this certificate and not allow access to the site.

<https://support.mozilla.org/en-US/questions/1012036>

You will need to install a proper SSL certificate.

Mailgateway

Install the Hubzero Mailgateway

```
sudo yum install -y hubzero-mailgateway
```

Configure the Hubzero Mailgateway

```
sudo hzcms configure mailgateway --enable
```

OpenLDAP

Install hubzero-openldap

```
sudo yum install -y hubzero-openldap
```

```
sudo service slapd start  
sudo chkconfig slapd on  
sudo chkconfig sssd on
```

Configure OpenLDAP database

```
sudo hzldap init dc=hubname,dc=org  
sudo hzcms configure ldap --enable  
sudo hzldap syncusers
```

Test

```
sudo getent passwd
```

You should see an entry for user 'admin' toward the end of the list if everything is working correctly.

WebDAV

Install WebDAV

```
sudo yum install -y hubzero-webdav
```

Configure WebDAV

```
sudo hzcms configure webdav --enable
```

Test

```
sudo ls -l /webdav/home/admin  
total 0
```

Browse to your site's `https /webdav` address (e.g. `https://myhub/webdav`). You should get prompted for a username and password. Use the admin account. You should see a directory listing including the file "mytest".

Now test using a WebDAV client.

```
sudo yum install -y cadaver  
sudo cadaver https://localhost/webdav
```

You will be prompted to accept self signed certificate (if it is still installed) and then to enter your username and password. Use the 'admin' account again to test. When you get the "dav:/webdav/>" prompt just enter "ls" and it should show the test file.

Finally clean up test case

```
sudo yum remove cadaver
```

Troubleshooting

If the test doesn't work, check if the fuse kernel module is loaded

```
sudo lsmod | grep fuse  
fuse                54176  0
```

If there is no output then try starting the kernel module manually

```
sudo modprobe fuse
```

Then try the test again

Subversion

Install

```
sudo yum install -y hubzero-subversion
```

Configure

```
sudo hzcms configure subversion --enable
```

Trac

Install

```
sudo yum install -y hubzero-trac
```

Configure

```
sudo hzcms configure trac --enable
```

Forge

Install

```
sudo yum install -y hubzero-forge
```

Configure

```
sudo hzcms configure forge --enable
```

OpenVZ

Install

```
sudo yum install -y hubzero-openvz-repo
```

Then install

```
sudo yum install -y hubzero-openvz
```

Configure

```
sudo hzcms configure openvz --enable
```

If configuration is successful it should prompt you to reboot the server to activate the new kernel.

```
sudo reboot
```

Test

```
sudo vzlist  
Container(s) not found
```

Or it will list the containers currently running if you check this on a running hub. The salient point being that the command doesn't issue any kind of error message.

Maxwell Client

Install

```
sudo yum install -y hubzero-mw2-client
sudo yum install -y hubzero-expire-sessions
```

Configure

```
sudo hzcms configure mw2-client --enable
sudo service expire-sessions start
sudo chkconfig expire-sessions on
```

Maxwell File Service

Install

```
sudo yum install -y hubzero-mw2-file-service
```

Maxwell Service

Install

```
sudo yum install -y hubzero-mw2-exec-service
sudo yum install -y hubzero-mw2-iptables-basic
sudo service hubzero-mw2-iptables-basic start
sudo chkconfig hubzero-mw2-iptables-basic on
```

Configure

```
sudo mkvztemplate amd64 wheezy ellie
```

```
sudo hzcms configure mw2-service --enable
sudo hzcms mw-
host add localhost up openvz pubnet sessions workspace fileserver
```

Test

```
sudo maxwell_service startvnc 1 800x600 24
```

Enter an 8 character password when prompted (e.g., "testtest")

This should result in a newly create OpenVZ session with an instance of a VNC server running inside of it. The output of the above command should look something like:

```
Reading passphrase:
testtest
===== begin /etc/vz/conf/hub-
session-5.0-amd64.umount =====
```

```
Removing /var/lib/vz/root/1 :root etc var tmp dev/shm dev
===== end /etc/vz/conf/hub-
```

INSTALLATION

```
session-5.0-amd64.umount =====
stunnel already running
Starting VE ...
===== begin /etc/vz/conf/1.mount =====
=====
Removing and repopulating: root etc var tmp dev

```

VNC Proxy Server

Install

```
sudo yum install -y hubzero-vncproxyd-ws
```

Configure

```
sudo hzvncproxyd-ws-config configure --enable  
sudo service hzvncproxyd-ws start  
sudo chkconfig hzvncproxyd-ws on
```

Install SSL certificate files

Copy your Apache SSL certificate files to `/etc/hzvncproxyd-ws/ssl-cert-hzvncproxyd-ws.pem` and `/etc/hzvncproxyd-ws/ssl-cert-hzvncproxyd-ws.key` and make sure they are readable by the user "hznproxy" to be found automatically by the proxy service.

If you are using a self-signed or otherwise invalid certificate the tool viewer will likely reject it and not work. If you are using the same certificate as your website and you allowed Chrome to use the invalid cert then the tool viewer will probably accept it. If you are using Firefox the tool viewer will always reject the invalid certificate. Always use a valid SSL certificate with hzvncproxyd-ws.

telequotad

Install

```
sudo yum install -y hubzero-telequotad
```

```
sudo service telequotad start  
sudo chkconfig telequotad on
```

Configure

In order for filesystems quotas to work they must be enabled when they are mounted. Determine which filesystem contains your home directories and add "quota" to the mount option of the corresponding entry in the `/etc/fstab` file. Only the filesystem with `/home` on it matters to telequotad.

If quotas weren't already in affect, the run something like the following (depending on your filesystem configuration) to start up the quota system. The following example assumes you want to enable quotas at the root level

```
sudo mount -oremount /home  
sudo quotacheck -cugm /home  
sudo quotacheck -avugm  
sudo quotaon -u /home
```

Test

```
sudo repquota -a
```

Should show disk usage for all users.

Workspace

Install

```
sudo yum install -y hubzero-app
sudo yum install -y hubzero-app-workspace
sudo hubzero-
app install --publish /usr/share/hubzero/apps/workspace-1.3.hza
```

Test

You should then be able to log in to the site and see the "Workspace" tool in the tool list and launch it in your browser.

Filexfer

Install

```
sudo yum install -y hubzero-filexfer-xlate
```

Configure

```
sudo hzcms configure filexfer --enable
```

Rappture

Install

```
sudo yum install -y hubzero-rappture-deb7
```

Configure

Rappture is used from inside a container and needs several other packages installed to allow use of all its features. This process has been simplified by using the `hubzero-rappture-session` which only contains the dependencies needed to pull in these other packages.

```
sudo chroot /var/lib/vz/template/debian-7.0-amd64-maxwell  
apt-get update; apt-get upgrade  
apt-get install -y hubzero-rappture-session  
exit
```

A workspace may need to be opened and closed a few times before the changes to the session template appear in a workspace.

Test

A user must setup their runtime environment in order to use the Rappture toolkit. Run the following command inside a Workspace tool session before attempting to run any Rappture tests.

```
use rappture
```

Rappture comes with several demonstration scripts that can effectively test many parts of the package. These demonstrations must be copied to a user's home directory within a workspace before running.

```
$ mkdir examples
```

INSTALLATION

```
$ cp -r /apps/share/rappture/examples/* examples/.  
$ cd examples  
$ ./demo.bash
```

A window should open on the workspace showing that part of the demonstration. Close that window to see the next demonstration. Some demonstrations may need something inputted to work properly (such as the graphing calculator).

Submit

Introduction

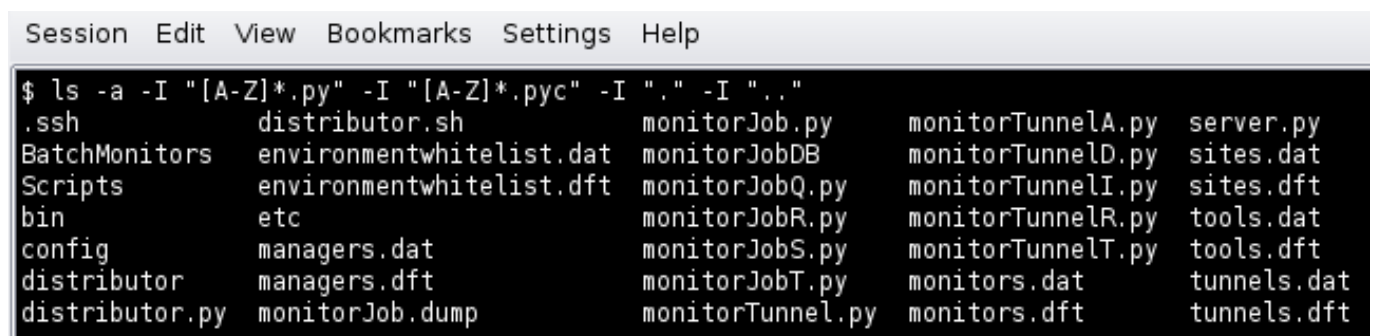

The submit command provides a means for HUB end users to execute applications on remote resources. The end user is not required to have knowledge of remote job submission mechanics. Jobs can be submitted to traditional queued batch systems including PBS and Condor or executed directly on remote resources.

Installation

```
sudo yum install -y hubzero-submit-pegasus
sudo yum install -y hubzero-submit-condor
sudo yum install -y hubzero-submit-common
sudo yum install -y hubzero-submit-server
sudo yum install -y hubzero-submit-distributor
sudo yum install -y hubzero-submit-monitors
```

```
sudo hzcms configure submit-server --enable
sudo service submit-server start
sudo chkconfig submit-server on
```

At completion of the yum install commands several files will be located in the directory /opt/submit. Excluding python files, the directory listing should like the following:

```
Session Edit View Bookmarks Settings Help
$ ls -a -I "[A-Z]*.py" -I "[A-Z]*.pyc" -I "." -I ".."
.ssh          distributor.sh      monitorJob.py      monitorTunnelA.py  server.py
BatchMonitors environmentwhitelist.dat monitorJobDB        monitorTunnelD.py  sites.dat
Scripts       environmentwhitelist.dft monitorJobQ.py      monitorTunnelI.py  sites.dft
bin           etc                monitorJobR.py     monitorTunnelR.py  tools.dat
config        managers.dat       monitorJobS.py     monitorTunnelT.py  tools.dft
distributor   managers.dft       monitorJobT.py     monitors.dat       tunnels.dat
distributor.py monitorJob.dump     monitorTunnel.py   monitors.dft       tunnels.dft
```

Configuration

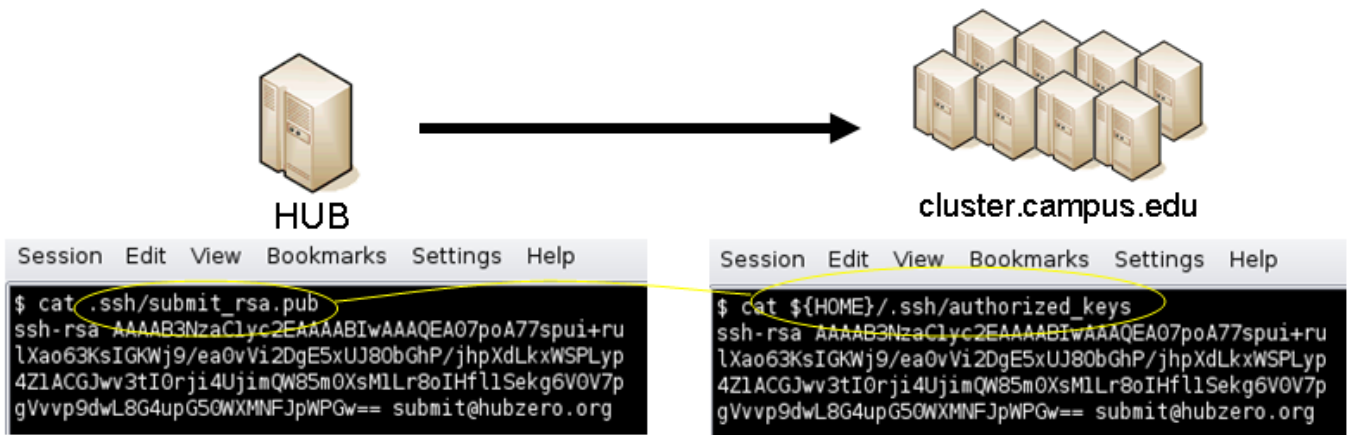

Submit provides a mechanism to execute jobs on machines outside the HUB domain. To

INSTALLATION

accomplish this feat, some configuration is required on the HUB and some additional software must be installed and configured on hosts in remote domains. Before attempting to configure submit it is necessary to obtain access to the target remote domain(s). The premise is that a single account on the remote domain will serve as an execution launch point for all HUB end users. It is further assumed that access to this account can be made by direct ssh login or using an ssh tunnel (port forwarding).

Having attained account access to one or more remote domains, it is possible to proceed with submit configuration. To get started, the ssh public generated by the installation should be transferred to the remote domain host(s).

HUB Configuration

The behavior of submit is controlled through a set of configuration files. The configuration files contain descriptions of the various parameters required to connect to a remote domain, exchange files, and execute simulation codes. There are separate files for defining remote sites, staged tools, multiprocessor managers, file access controls, permissible environment variables, remote job monitors, and ssh tunneling. Most parameters have default values and it is not required that all parameters be explicitly defined in the configuration files. A simple example is given for each category of configuration file.

HUB

- Remote sites
- Staged tools
- Remote job monitors
- Multi-processor managers
- Permissible environment variables
- ssh tunnels

Sites

Remote sites are defined in the file `sites.dat`. Each remote site is defined by a stanza indicating an access mechanism and other account and venue specific information. Defined keywords are

- `[name]` - site name. Used as command line argument (`-v/--venue`) and in `tools.dat` (destinations)
- `venues` - comma separated list of hostnames. If multiple hostnames are listed one site will chosen at random.
- `tunnelDesignator` - name of tunnel defined in `tunnels.dat`.
- `siteMonitorDesignator` - name of site monitor defined in `monitors.dat`.
- `venueMechanism` - possible mechanisms are `ssh` and `local`.
- `remoteUser` - login user at remote site.
- `remoteBatchAccount` - some batch systems requirement that an account be provided in addition to user information.
- `remoteBatchSystem` - the possible batch submission systems include `CONDOR`, `PBS`, `SGE`, and `LSF`. `SCRIPT` may also be specified to specify that a script will be executed directly on the remote host.
- `remoteBatchQueue` - when `remoteBatchSystem` is `PBS` the queue name may be specified.
- `remoteBatchPartition` - slurm parameter to define partition for remote job
- `remoteBatchPartitionSize` - slurm parameter to define partition size, currently for BG machines.
- `remoteBatchConstraints` - slurm parameter to define constraints for remote job
- `parallelEnvironment` - sge parameter
- `remoteBinDirectory` - define directory where shell scripts related to the site should be kept.
- `remoteApplicationRootDirectory` - define directory where application executables are located.
- `remoteScratchDirectory` - define the top level directory where jobs should be executed. Each job will create a subdirectory under `remoteScratchDirectory` to isolated jobs from each other.
- `remotePpn` - set the number of processors (cores) per node. The PPN is applied to `PBS` and `LSF` job description files. The user may override the value defined here from the command line.
- `remoteManager` - site specific multi-processor manager. Refers to definition in

managers.dat.

- remoteHostAttribute - define host attributes. Attributes are applied to PBS description files.
- stageFiles - A True/False value indicating whether or not files should be staged to remote site. If the the job submission host and remote host share a file system file staging may not be necessary. Default is True.
- passUseEnvironment - A True/False value indicating whether or not the HUB 'use' environment should passed to the remote site. Default is False. True only makes sense if the remote site is within the HUB domain.
- arbitraryExecutableAllowed - A True/False value indicating whether or not execution of arbitrary scripts or binaries are allowed on the remote site. Default is True. If set to False the executable must be staged or emanate from /apps. (deprecated)
- executableClassificationsAllowed - classifications accepted by site. Classifications are set in appaccess.dat
- members - a list of site names. Providing a member list gives a layer of abstraction between the user facing name and a remote destination. If multiple members are listed one will be randomly selected for each job.
- state - possible values are enabled or disabled. If not explicitly set the default value is enabled.
- failoverSite - specify a backup site if site is not available. Site availability is determined by site probes.
- checkProbeResult - A True/False value indicating whether or not probe results should determine site availability. Default is True.
- restrictedToUsers - comma separated list of user names. If the list is empty all users may garner site access. User restrictions are applied before group restrictions.
- restrictedToGroups - comma separated list of group names. If the list is empty all groups may garner site access.
- logUserRemotely - maintain log on remote site mapping HUB id, user to remote batch job id. If not explicitly set the default value is False.
- undeclaredSiteSelectionWeight - used when no site is specified to choose between sites where selection weight > 0.
- minimumWallTime - minimum walltime allowed for site or queue. Time should be expressed in minutes.
- maximumWallTime - maximum walltime allowed for site or queue. Time should be expressed in minutes.
- minimumCores - minimum number of cores allowed for site or queue.
- maximumCores - maximum number of cores allowed for site or queue.
- pegasusTemplates - pertinent pegasus templates for site, rc, and transaction files.

An example stanza is presented for a site that is accessed through ssh.

INSTALLATION

```
Session Edit View Bookmarks Settings Help
$ hostname -f
cluster.campus.edu
$ whoami
yourhub
$ echo ${HOME}
/home/yourhub
$ printenv | SCRATCH
CLUSTER_SCRATCH=/scratch/yourhub
```

```
[cluster]
venues = cluster.campus.edu
remotePpn = 8
remoteBatchSystem = PBS
remoteBatchQueue = standby
remoteUser = yourhub
remoteManager = mpich-intel64
venueMechanism = ssh
remoteScratchDirectory = /scratch/yourhub
siteMonitorDesignator = clusterPBS
```

Tools

Staged tools are defined in the file tools.dat. Each staged tool is defined by a stanza indicating an where a tool is staged and any access restrictions. The existence of a staged tool at multiple sites can be expressed with multiple stanzas or multiple destinations within a single stanza. If the tool requires multiprocessors a manager can also be indicated. Defined keywords are

- [name] - tool name. Used as command line argument to execute staged tools. Repeats are permitted to indicate staging at multiple sites.
- destinations - comma separated list of destinations. Destination may exist in sites.dat or be a grid site defined by a ClassAd file.
- executablePath - path to executable at remote site. The path may be given as an absolute path on the remote site or a path relative to remoteApplicationRootDirectory defined in sites.dat.
- restrictedToUsers - comma separated list of user names. If the list is empty all users may garner tool access. User restrictions are applied before group restrictions.
- restrictedToGroups - comma separated list of group names. If the list is empty all groups may garner tool access.
- environment - comma separated list of environment variables in the form e=v.
- remoteManager - tool specific multi-processor manager. Refers to definition in managers.dat. Overrides value set by site definition.
- state - possible values are enabled or disabled. If not explicitly set the default value is

INSTALLATION

enabled.

An example stanza is presented for a staged tool maintained in the yourhub account on a remote site.

cluster.campus.edu

antares.x betelgeuse.x polaris.x sun.x
```

```
[earth]
destinations = cluster
executablePath = ${HOME}/apps/planets/bin/earth.x
remoteManager = mpich-intel
```

```
[sun]
destinations = cluster
executablePath = ${HOME}/apps/stars/bin/sun.x
remoteManager = mpich-intel
```

Monitors

Remote job monitors are defined in the file monitors.dat. Each remote monitor is defined by a stanza indicating where the monitor is located and to be executed. Defined keywords are

- [name] - monitor name. Used in sites.dat (siteMonitorDesignator)
- venue - hostname upon which to launch monitor daemon. Typically this is a cluster headnode.
- venueMechanism - monitoring job launch process. The default is ssh.
- tunnelDesignator - name of tunnel defined in tunnels.dat.

INSTALLATION

- remoteUser - login user at remote site.
- remoteBinDirectory - define directory where shell scripts related to the site should be kept.
- remoteMonitorCommand - command to launch monitor daemon process.
- state - possible values are enabled or disabled. If not explicitly set the default value is enabled.

An example stanza is presented for a remote monitor tool used to report status of PBS jobs.

```
Session Edit View Bookmarks Settings Help
$ qstat -u yourhub
cluster.campus.edu:
Job ID      Username Queue  Jobname SessID NDS TSK Req'd Elap
-----
9823388.steele- yourhub standby earth 3508 2 16 04:00 R 02:15
9824065.steele- yourhub standby sun 9975 1 1 04:00 R 01:26
```

```
[clusterPBS]
venue = cluster.campus.edu
remoteUser = yourhub
remoteMonitorCommand = ${HOME}/SubmitMonitor/monitorPBS.py
```

Multi-processor managers

Multiprocessor managers are defined in the file managers.dat. Each manager is defined by a stanza indicating the set of commands used to execute a multiprocessor simulation run. Defined keywords are

- [name] - manager name. Used in sites.dat and tools.dat.
- computationMode - indicate how to use multiple processors for a single job. Recognized values are mpi, parallel, and matlabmpi. Parallel application request multiprocess have there own mechanism for inter process communication. Matlabmpi is used to enable the an Matlab implementation of MPI.
- preManagerCommands - comma separated list of commands to be executed before the manager command. Typical use of pre manager commands would be to define the environment to include a particular version of MPI amd/or compiler, or setup MPD.
- managerCommand - manager command commonly mpirun. It is possible to include strings that will be sustituted with values defined from the command line.
- postManagerCommands - comma separated list of commands to be executed when the manager command completes. A typical use would be to terminate an MPD setup.

INSTALLATION

- `mpiRankVariable` - define environment variable set by manager command to define process rank. Recognized values are: `MPIRUN_RANK`, `GMPI_ID`, `RMS_RANK`, `MXMPI_ID`, `MSTI_RANK`, `PMI_RANK`, and `OMPI_MCA_ns_nds_vpid`. If no variable is given an attempt is made to determine process rank from command line arguments.
- `environment` - comma separated list of environment variables in the form `e=v`.
- `moduleInitialize` - initialize module script for `sh`
- `modulesUnload` - modules to be unloaded clearing way for replacement modules
- `modulesLoad` - modules to load to define mpi and other libraries
- `state` - possible values are enabled or disabled. If not explicitly set the default value is enabled.

An example stanza is presented for a typical MPI instance. The given command should be suitable for `/bin/sh` execution.

```
Session Edit View Bookmarks Settings Help
$ module available mpich
----- /opt/modules/modulefiles -----
mpich-intel/10.1.025          mpich-intel/9.1.045
mpich-intel/11.1.038(default)  mpich2-intel/11.1.038(default)

$ module load mpich-intel/11.1.038
$ which mpirun
/apps/rhel5/mpich-1.2.7p1/p4-intel-11.1.038/bin/mpirun
```

```
[mpich-intel]
preManagerCommands = . ${MODULESHOME}/init/sh, module load mpich-
intel/11.1.038
managerCommand = mpirun -machinefile ${PBS_NODEFILE} -np NPROCESSORS
```

The token `NPROCESSORS` is replaced by an actual value at runtime.

File access controls

Application or file level access control is described by entries listed in the file `appaccess.dat`. The ability to transfer files from the HUB to remote sites is granted on a group basis as defined by white and black lists. Each list is given a designated priority and classification. In cases where a file appears on multiple lists, the highest priority takes precedence. Simple wildcard operators are allowed in the filename declaration allowing for easy listing of entire directories. Each site lists acceptable classification(s) in `sites.dat`. Defined keywords are

- `[group]` - group name.
- `whitelist` - comma separated list of paths. Wildcards allowed.

INSTALLATION

- blacklist - comma separated list of paths. Wildcards allowed.
- priority - higher priority wins
- classification - apps or user. user class are treated as arbitrary executables.
- state - possible values are enabled or disabled. If not explicitly set the default value is enabled.

An example file giving permissions reminiscent of those defined in earlier submit releases is presented here

```
[public]
whitelist = /apps/*.
priority = 0
classification = apps
```

```
[submit]
whitelist = ${HOME}/*.
priority = 0
classification = home
```

The group public is intended to include all users. Your system may use a different group such as users for this purpose. The definitions shown here allow all users access to files in /apps where applications are published. Additionally members of the submit group are allowed to send files from their \$HOME directory.

Environment variables

Legal environment variables are listed in the file environmentwhitelist.dat. The objective is to prevent end users from setting security sensitive environment variables while allowing application specific variables to be passed to the remote site. Environment variables required to define multiprocessor execution should also be included. The permissible environment variables should be entered as a simple list - one entry per line. An example file allowing use of a variables used by openmp and mpich is presenter here.

```
# environment variables listed here can be specified from the command
line with -e/--env option. Attempts to specify other environment varia
bles will be ignored and the values will not be passed to the remote s
ite.
```

INSTALLATION

OMP_NUM_THREADS

MPICH_HOME

Tunnels

In some circumstances, access to clusters is restricted such that only a select list of machines is allowed to communicate with the cluster job submission node. The machines that are granted such access are sometimes referred to as gateways. In such circumstances, ssh tunneling or port forwarding can be used to submit HUB jobs through the gateway machine. Tunnel definition is specified in the file tunnels.dat. Each tunnel is defined by a stanza indicating gateway host and port information. Defined keywords are

- [name] - tunnel name.
- venue - tunnel target host.
- venuePort - tunnel target port.
- gatewayHost - name of the intermediate host.
- gatewayUser - login user on gatewayHost.
- localPortOffset - local port offset used for forwarding. Actual port is localPortMinimum + localPortOffset

An example stanza is presented for a tunnel between the HUB and a remote venue by way of an accepted gateway host.

```
[cluster]
venue = cluster.campus.edu
venuePort = 22
gatewayHost = gateway.campus.edu
gatewayUser = yourhub
localPortOffset = 1
```

Initialization Scripts and Log Files

The submit server and job monitoring server must be started as daemon processes running on the the submit host. If ssh tunneling is going to be used an addition server must be started as a daemon process. Each daemon process writes to a centralized log file facilitating error recording and debugging.

Initialize daemon scripts

Scripts for starting the server daemons are provided and installed in /etc/init.d. The default settings for when to start and terminate the scripts are adequate.

Log files

Submit processes log information to files located in the /var/log/submit directory tree. The exact location varies depending on the vintage of the installation. Each process has its own log file. The three most important log files are submit-server.log, distributor.log, and monitorJob.log.

submit.log

The submit-server.log file tracks when the submit server is started and stopped. Each connection from the submit client is logged with the command line and client ip address reported. All log entries are timestamped and reported by submit-server process ID (PID) or submit ID (ID:) once one has been assigned. Entries from all jobs are simultaneously reported and intermingled. The submit ID serves as a good search key when tracing problems. Examples of startup, job execution, and termination are given here. The job exit status and time metrics are also recorded in the MySQL database JobLog table.

monitorJob.log

The monitorJob.log file tracks the invocation and termination of each remotely executed job monitor. The remote job monitors are started on demand when job are submitted to remote sites. The remote job monitors terminate when all jobs complete at a remote site and no new activity has been initiated for a specified amount of time - typically thirty minutes. A typical report should look like:

```
[Sun Aug 26 17:29:16 2012] (1485) *****
[Sun Aug 26 17:29:16 2012] (1485) * distributor job monitor started *

```

It is imperative that the job monitor be running in order for notification of job progress to occur. If users report that their job appears to hang check to make sure the job monitor is running. If necessary take corrective action and restart the daemon.

monitorTunnel.log

The monitorTunnel.log file tracks invocation and termination of each ssh tunnel connection. If users report problems with job submission to sites accessed via an ssh tunnel this log file should be checked for indication of any possible problems.

Remote Domain Configuration

For job submission to remote sites via ssh it is necessary to configure a remote job monitor and a set of scripts to perform file transfer and batch job related functions. A set of scripts can be used for each different batch submission system or in some cases they may be combined with appropriate switching based on command line arguments. A separate job monitor is need for each batch submission system. Communication between the HUB and remote resource via ssh requires inclusion of a public key in the authorized_keys file.

- ssh public key
- Batch job monitoring daemon
- File transfer scripts
- Batch job scripts

Job monitor daemon

A remote job monitor runs a daemon process and reports batch job status to a central job monitor located on the HUB. The daemon process is started by the central job monitor on demand. The daemon terminates after a configurable amount of inactivity time. The daemon code needs to be installed in the location declared in the monitors.dat file. The daemon requires some initial configuration to declare where it will store log and history files. The daemon does not require any special privileges any runs as a standard user. Typical configuration for the daemon looks like this:

```
$ cat monitors.dat
[clusterPBS]
venue = cluster.campus.edu
remoteUser = yourhub
remoteMonitorCommand = ${HOME}/Submit/monitorPBS.py
```

```
Session Edit View Bookmarks Settings Help
$ cd ${HOME}/Submit
$ ls -R
.:
LogMessage.py LogMessage.pyc logs monitorPBS.history monitorPBS.py
./logs:
monitorPBS.log
```

```
$ cat ${HOME}/Submit/monitorPBS.py
...
SITEDESIGNATOR = "clusterPBS"
MONITORROOT = os.path.join(os.sep, 'home', 'yourhub', 'Submit')
QSTATCOMMAND = "/usr/pb/bin/qstat -u yourhub"
MONITORLOGLOCATION = os.path.join(MONITORROOT, 'logs')
...
```

The directory defined by MONITORLOGLOCATION needs to be created before the daemon is started. Sample daemon scripts used for PBS, LSF, SGE, Condor, Load Leveler, and Slurm batch systems are included in directory BatchMonitors.

File transfer and batch job scripts

The simple scripts are used to manage file transfer and batch job launching and termination.

INSTALLATION

The location of the scripts is entered in sites.dat.

```
$ cat sites.dat
[clusterPBS]
venue = cluster.campus.edu
remoteUser = yourhub
remoteBinDirectory = ${HOME}/bin
```

```
Session Edit View Bookmarks Settings Help
$ cd ${HOME}/bin
$ ls
cleanupjob.sh      receiveinput.sh    reportbatchjobstatus.sh  transmitresults.sh
killbatchjob.sh   remotematlab.sh    submitbatchjob.sh        waitforbatchjob.sh
```

Examples scripts suitable for use with PBS, LSF, Condor, Load Leveler, and Slurm are included in directory Scripts. After modifications are made to monitors.dat the central job monitor must be notified. This can be accomplished by stopping and starting the submon daemon or a HUP signal can be sent to the monitorJob.py process.

File transfer - input files

Receive compressed tar file containing input files required for the job on stdin. The file transferredTimestampFile is used to determine what newly created or modified files should be returned to the HUB.

```
receiveinput.sh jobWorkingDirectory jobScratchDirectory transferredTimestampFile
```

Batch job script - submission

Submit batch job using supplied description file. If arguments beyond job working directory and batch description file are supplied an entry is added to the remote site log file. The log file provides a record relating the HUB end user to the remote batch job identifier. The log file should be placed at a location agreed upon by the remote site and HUB.

```
submitbatchjob.sh jobWorkingDirectory jobScratchDirectory jobDescriptionFile
```

INSTALLATION

The jobId is returned on stdout if job submission is successful. For an unsuccessful job submission the returned jobId should be -1.

File transfer - output files

Return compressed tar file containing job output files on stdout.

```
transmitresults.sh jobWorkingDirectory
```

File transfer - cleanup

Remove job specific directory and any other dangling files

```
cleanupjob.sh jobWorkingDirectory jobScratchDirectory jobClass
```

Batch job script - termination

Terminate given remote batch job. Command line arguments specify job identifier and batch system type.

```
killbatchjob.sh jobId jobClass
```

Batch job script - post process

For some jobClasses it is appropriate to preform standard post processing actions. An example of such a jobClass is Pegasus.

```
postprocessjob.sh jobWorkingDirectory jobScratchDirectory jobClass
```

Access Control Mechanisms

By default tools and sites are configured so that access is granted to all HUB members. In some cases it is desired to restrict access to either a tool or site to a subset of the HUB membership. The keywords `restrictedToUsers` and `restrictedToGroups` provide a mechanism to apply restrictions accordingly. Each keyword should be followed by a list of comma separated values

INSTALLATION

of userids (logins) or groupids (as declared when creating a new HUB group). If user or group restrictions have been declared upon invocation of submit a comparison is made between the restrictions and userid and group memberships. If both user and group restrictions are declared the user restriction will be applied first, followed by the group restriction.

In addition to applying user and group restrictions another mechanism is provided by the `executableClassificationsAllowed` keyword in the sites configuration file. In cases where the executable program is not pre-staged at the remote sites the executable needs to be transferred along with the user supplied inputs to the remote site. Published tools will have their executable program located in the `/apps/tools/revision/bin` directory. For this reason submitted programs that reside in `/apps` are assumed to be validated and approved for execution. The same cannot be said for programs in other directories. The common case where such a situation arises is when a tool developer is building and testing within the HUB workspace environment. To grant a tool developer the permission to submit such arbitrary applications the site configuration must allow arbitrary executables and the tool developer must be granted permission to send files from their `$HOME` directory. Discrete permission can be granted on a file by file basis in `appaccess.dat`.
