Hardening the Content Management System

Application Scanning

A web application scanner will look for typical mistakes made in PHP applications: XSS, CSRF and SQL injections, and more. We use AppScan, but many free application scanners are available. You should scan any component you code yourself, or 3rd party component, that is not part of the HUBzero release. Also, if you modify a component in a HUBzero release, you should scan it for vulnerabilities the change may have introduced. If you find a vulnerability in the HUBzero release itself, please file a ticket at hubzero.org!

CMS-Controlled Fail2Ban Jail

Configuration and Details

Objective

To have the CMS handle user login banning in an attempt to deter brute force attacks.

CMS Configuration Page

The following settings are accessible from the CMS administrative backend.

These options are accessible by going to the User Menu Members and Member Options.

User Password Reset Limit

The number of password resets per time period is limited. If the user attempts to reset their password at a threshold deemed by the HUB administrator as excessive, the following message is displayed.

User Failed Login Limit

The number of failed logins per time period is limited. If the user attempts to reset their password at a threshold deemed by the HUB administrator as excessive, the following message is displayed. This means that an individual's account is temporarily blocked until the time period expires.

IPbased Blocked User Limit

When the threshold of blocked user accounts per IP network is met, the CMS will trigger a Fail2Ban rule which will block incoming requests from an IP address for a period of time. This is the last line of defense as blocking an IP address may have unintended consequences such as

blocking a NATed IP address which several valid users are using to access the hub.

Assumptions

This approach assumes that the system administrator has configured a jail and a system user account to execute (with sudo) Fail2Ban via the fail2banclient utility.

On Debian Hosts, Fail2Ban should be version 0.9.5.

0.9.51~nd70+1 from http://neuro.debian.net/debian/ wheezy/main amd64 Packages

Setup & Configuration

There are a number of subsystems which need to be configured for this scheme to work properly.

sudo Configuration

A privileged user which can execute:

(root) NOPASSWD: /usr/bin/fail2banclient set hublogin banip [09.]* (root) NOPASSWD: /usr/bin/fail2banclient set hublogin unbanip [09.]*

This can be accomplished by adding a sudoers rule in /etc/sudoers.d/ that looks like:

wwwdata ALL=(root)NOPASSWD: /usr/bin/fail2banclient set hublogin banip [09.]*

Fail2Ban Configuration

The system administrator should configure Fail2Ban to create jails which the CMS can add offending IP address into. The amount of time that the ban is valid is configured in Fail2Ban.

The CMS will simply add IP addresses to the Fail2Ban jail which will trigger the Ban Action as specified in the rule set.

The following configuration are more of an example than anything. A seasoned system administrator will have crafted better rules.

[Sample] Jail Configuration

```
#

# JAILS

# /etc/fail2ban/jail.local

#

[hublogin] enabled  = true

port      = http,https filter      = hublogin

logpath = /var/log/messages banaction = hubloginfailure bantime = 600

findtime = 1

maxretry = 1
```

[Sample] Filter Configuration

/etc/fail2ban/filter.d/hublogin.conf

```
# Fail2Ban configuration file

#

[Definition]

# Option:  failregex

# Notes.:  Regexp to catch known spambots and software alike. Please verify

#          that it is your intent to block IPs which were driven by

#          abovementioned bots.

# Values:  TEXT

#

#We choose something that will never happen

# Since the CMS will control IP’s placed in the jails failregex =
^<HOST>thisfilterwillneverbefound

# Option:  ignoreregex

# Notes.:  regex to ignore. If this regex matches, the line is ignored.

# Values:  TEXT

#

ignoreregex =
```

[Sample] Action Configuration

Fail2Ban configuration file

cat /etc/fail2ban/action.d/hubloginfailure.conf [INCLUDES]

before = iptablescommon.conf

[Definition]

Option: actionstart

Notes.: command executed once at the start of Fail2Ban.

Values: CMD

#

actionstart = iptables N fail2banhublogin

iptables A INPUT j DROP

iptables I INPUT p tcp j fail2banhublogin

Option: actionstop

Notes.: command executed once at the end of Fail2Ban

Values: CMD

#

actionstop = iptables D fail2banhublogin p tcp j fail2banhublogin iptables F fail2banhublogin

iptables X fail2banhublogin

Option: actioncheck

Notes.: command executed once before each actionban command

Values: CMD

#

actioncheck = iptables n L fail2banhublogin | grep q fail2banhublogin

Option: actionban

Notes.: command executed when banning an IP. Take care that the

command is executed with Fail2Ban user rights.

Tags: <ip> IP address

<failures> number of failures

<time> unix timestamp of the ban time

Values: CMD

#

actionban = iptables I fail2banhublogin p tcp dport 443 s <ip> j DROP

iptables I fail2banhublogin p tcp dport

80 s <ip> j DROP

Option: actionunban

Notes.: command executed when unbanning an IP. Take care that the

command is executed with Fail2Ban user rights.

Tags: <ip> IP address

<failures> number of failures

<time> unix timestamp of the ban time

Values: CMD

#

actionunban = iptables D fail2banhublogin p tcp dport 443 s <ip> j DROP iptables D fail2ban-hublogin p tcp dport 80 s <ip> j DROP

[Init]

Defaut name of the chain

#

name = DEFAULT

Option: protocol

Notes.: internally used by config reader for interpolations.

Values: [tcp | udp | icmp | all] Default: tcp

#

protocol = tcp

Option: chain

Notes specifies the iptables chain to which the fail2ban rules should be

added

Values: STRING Default: INPUT chain = INPUT

[Sample] Banned IP address results root@example:/var/www/example# fail2banclient status hublogin Status for the jail: hublogin

User Impact

When a large number of people intend on using the CMS, it may be wise to temporarily disable this feature (e.g. conference, class activity, etc). In the past, many conference goers have mistyped their password in a short period of time creating a false positive for normal Fail2Ban operation. This risk is mitigated by the fact that the number of blocked users is observed before triggering Fail2Ban.
