Invoke scripts for Jupyter notebooks

The hub tool invoke script is located in the tool's middleware/ subdirectory. When you first create a tool, the basic invoke script provided must be edited to work with Jupyter notebook tools.

This writeup shows you how to create Jupyter tools with three different appearances: notebook, App, and Tool mode.

invoke_app and start_jupyter

To deploy a Jupyter notebook as a tool on your hub, you call the invoke_app executable, which in turn calls start_jupyter. Each have their own arguments:

arguments for start_jupyter

-h, --help   show this help message and exit.
-d           Show debug (verbose) output.
-t           Run as a Tool with no notebook controls.
-c           Copy instead of link notebook files.
-A           Run in AppMode.
-T dir       Search for notebook starting in dir.
--themes     Enable notebook themes

arguments for invoke_app

-t Tool name
-C command to execute
-r Rappture version to use (normally specify none for notebook tools)
-w headless
-u environment package (repeat as necessary)

invoke_app: starting point

The basic invoke script for Jupyter notebooks looks like this:

```
/usr/bin/invoke_app "$@" -t TOOLNAME \
   -C "start_jupyter -T @tool APP.ipynb" \
   -r none \ 
       -w headless \
```
-u anaconda-X

Invoking a Jupyter tool this way gives a notebook with all its code cells displayed to the user.

Where:

- TOOLNAME is the short name of the tool
- APP is the name of the main notebook that runs the tool
- anaconda-X is the current anaconda installation

**start_jupyter arguments**

Control the way the notebook appears when run as a tool, using the arguments passed to the start_jupyter executable.

You can run a Jupyter tool in three ways:

- notebook mode, in which all code cells are displayed to the user (shown above)
- app mode, in which code cells are initially hidden but can be displayed
- tool mode, in which code cells are hidden and cannot be displayed

**for App Mode**

For a notebook tool that hides its code cells and shows only the UI and markdown elements on initial run, add the -A argument in the start_jupyter call:

```
/usr/bin/invoke_app "@$" -t TOOLNAME \ 
  -C "start_jupyter -A -T @tool APP.ipynb" \ 
  -u anaconda-X \ 
    -w headless \ 
  -r none
```

The tool user can toggle the tool's "Edit App" button to show the underlying code cells, making this a great teaching/demo option.

**NOTE** that this differs from the invoke_app -A argument.

**for Tool Mode**

To permanently hide code cells from the user in App Mode, specify the -A and -t arguments in
the start_jupyter call:

/usr/bin/invoke_app "@" -t TOOLNAME \
   -C "start_jupyter -A -t -T @tool APP.ipynb" \
   -u anaconda-X \
   -w headless \
   -r none

The Edit App button will not be displayed to the tool user.

NOTE that this differs from the invoke_app -t argument.

errors

specify no rappture

Error:

Running the tool's invoke script from a workspace, returns:

"could not find a rappture installation: RAPPTURE_PATH=,"

Fix:

Be sure to supply the "-r none" argument in the invoke_app call, as above. No quotation marks are needed.
